

$$R - X \xrightarrow{2 \text{ Li}}_{\text{Ether}} \begin{array}{c} R - \text{Li} \xrightarrow{\text{CuX}} & R \\ + \text{LiX} \end{array} \xrightarrow{R - \text{CuLi}}_{\text{Lithium dialkyl cuperate}} \\ \text{may be 1}^{\circ}, 2^{\circ} \text{ or } 3^{\circ} \end{array} \xrightarrow{R - \text{Li}}_{\text{Kix}} \begin{array}{c} R - \text{CuLi} \\ \text{Lithium dialkyl cuperate} \\ \text{Lithium dialkyl be 1}^{\circ} \\ R - R' + R - \text{Cu} + \text{Lix} \end{array}$$

[This method is used to prepare higher alkanes]. This method is particularly suitable for preparation of unsymmetrical alkanes].

$$CH_{3}CH_{2}Cl \xrightarrow{2 \text{ Li}} CH_{3}CH_{2} - \text{Li} + \text{LiCl} \xrightarrow{Cu} CH_{3} - CH_{2} - Cu\text{Li}$$

$$Ethyl chloride Ethyl Lithium Lithium Lithium dialkyl cupperate$$

$$LiBr + CH_3CH_2Cu + CH_3CH_2 - CH_2(CH_2)_3CH_3$$

n-heptane

4. By reduction of alcohols, aldehydes, ketones, carboxylic acid

$$R - CH_{2}OH \xrightarrow{\text{RedP/2HI}} R - CH_{3} + H_{2}O + I_{2}$$

$$CH_{3}CHO \xrightarrow{\text{RedP/4HI}} CH_{3}CH_{3} + H_{2}O + 2I_{2}$$

5. By wurtz reaction :

$$\mathbf{R} - \mathbf{X} + 2\mathbf{N}\mathbf{a} + \mathbf{R} - \mathbf{X} \xrightarrow{\text{ether}} \mathbf{R} - \mathbf{R} + 2\mathbf{N}\mathbf{a}\mathbf{X}$$

Example :

• $2Na + 2CH_{1}CH_{2}C$

[This method is useful for the prepration of symmetrical alkanes]

6. Decarboxylation (The process of eliminating CO₂ from carboxylic acid is called as decarboxylation)

$$\underset{\text{cid}}{\text{RCOONa}} + \underset{\text{(soda lime)}}{\text{NaOH}(CaO)} \xrightarrow{\Delta} R - H + Na_2CO_3$$

$$CH_3COONa + NaOH(CaO) \xrightarrow{\Delta} CH_4 + Na_2CO_3$$

[The alkane formed in this way always contain one carbon atom less than the carboxylic acid].

7. Kolbe's Electrolytic Method : A concentrated solution of the sodium or potassium salt of carboxylic acid is electrolysed.

 $R_1COOK + R_2COOK + 2H_2O \rightarrow R^1 - R^2 + 2CO_2 + H_2 + 2KOH$

[If \mathbf{R}_1 and \mathbf{R}_2 are different then $\mathbf{R}_1 - \mathbf{R}_1$ and $\mathbf{R}_2 - \mathbf{R}_2$ are also obtained]

other side products are – alkenes, esters, alcohols.

Practice Problems : 1. By Wurtz reaction, a mixture of methyl iodide and ethyl iodide gives propane (a) **(b)** ethane (c) butane (**d**) a mixture of the above three 2. Kolbe's synthesis of sodium salt of butanoic acid gives n-hexane isobutane n-butane(d) (a) **(b)** (c) propanone (CH₂)₃C — MgCl on reaction with D₂O produces 3. (CH₂)₂CD **(b)** (CH₂)₂OD (CD₂)₂CD (CD₃)₃OD (a) (c) (**d**) 4. Aq. solution of potassium acetate is electrolysed. Possible organic products are : CH,COOCH, (a) CH₁-CH₁ **(b)** CH,CH,CH,CH, both (a) and (b) are correct (c) (**d**) [Answers: (1) d (2) a (3) a (4) d] **C2 General Chemical properties of alkanes :** 3 1. Halogenation: $- \overset{|}{C} - H + X_2 \xrightarrow{250-400^{\circ}C} - \overset{|}{C} - X + HX$ Usually a mixture Reactivity $X_2: F_2 > Cl_2 > Br_2$ (I, does not react) $H: 3^{\circ} > 2^{\circ} > 1^{\circ} > CH_{3} - H$ Example: $\begin{array}{c} Cl_{2} & CH_{3} & CH_{3} \\ \hline 50-400^{\circ}C \end{array} \rightarrow CH_{3} - CH - CH_{2}Cl + CH_{3} - C - CH_{3} \\ \hline 100000 \\ \hline 100000 \\ \hline 100000 \\ \hline 100000 \\ \hline 10000 \\ \hline 1$ CH, $CH_3 - CH - CH_3$ **Chlorination:** Isobutane –ČH,CH, **Exception:** (45 %) (55%) $CH_{3}CH_{2}CH_{2}CH_{3} \xrightarrow{Cl_{2}} CH_{3}CH_{2}CH_{2} - Cl + CH_{3}CH_{2}CH - CH_{3}$ (28 %) (72%) $CH_{3} \xrightarrow{CH_{3}} Br_{2} \xrightarrow{CH_{3}} CH_{3} \xrightarrow{CH_{3}} H_{3}$ $CH_{3} \xrightarrow{CH_{3}} CH_{3} \xrightarrow{CH_{3}} H_{3}$ $H_{3} \xrightarrow{CH_{3}} H_{3} \xrightarrow$ **Bromination:** Br (over 99 %)

Conclusion :

- 1. Although both chlorination and bromination yield a mixture of isomers, the results given above shows that relative amounts of isomer differ markedly depending upon the halogen used.
- 2. Chlorination gives a mixture of isomers in which no one predominates. In bromination on contrast one isomer predominates to such an extent that as to be only product produced.

The factors determines the relative yields of isomeric products :

- 1. Probability Factor: This factor is based on the number of each kind of H-atom in the molecule. For example, In CH, CH, CH, CH, there are six equivalent 1°H's and four equivalent 2°H's. The ratio of abstraction of 1°H are thus 6 to 4 or 3 to 2.
- Reactivity of H^{\bullet} : The order of reactivity of H is $3^{\circ} > 2^{\circ} > 1^{\circ}$. 2.
- 3. **Reactivity of X**[•]: The more reactive Cl is less selective and more influenced by the probability factor. The less reactive Br is more selective and less influenced by the probability factor, as summarised by the reactivity-selectivity principle. If the attacking species is more reactive then it will be less selective, and yields will be closer to those expected from the probability factor.
- The rate of abstraction of hydrogen atoms is always found to follow the sequence $3^0 > 2^0 > 1^0$.
- At room temperature are 5: 3.8: 1 using these values we can predict the ratio of isomeric chlorine products from a given alkane.

Example :

$$\mathbf{CH_3CH_2CH_2CH_3} \xrightarrow[light, 25^0C]{Cl_2} \mathbf{CH_3CH_2CH_2CH_2CI} + \mathbf{CH_3CH_2CHCH_3}$$

$$\frac{n - Butyl Chloride}{sec - Butyl Chloride} = \frac{no. of 1^{0} H}{no. of 2^{0} H} \times \frac{reactivity of 1^{0} H}{reactivity of 2^{0} H}$$

$$= \frac{6}{4} \times \frac{1}{200} = \frac{6}{1500} = \frac{28\%}{700\%}$$

$$=\frac{6}{4}\times\frac{1}{3.8}=\frac{6}{15.2}=\frac{28\%}{72\%}$$

The same sequence of reactivity, $3^{\circ} > 2^{\circ} > 1^{\circ}$ is found in Bromination, but with enormously larger reactivity ratios. At 127°C the relative rate per hydrogen atom are 1600 : 82 : 1. Here, difference in reactivity are so marked so as to outweigh probability factor. Hence bromination is selective product.

In bromination of isobutane at 127°C

 $\frac{\text{Isobutyl bromide}}{\text{ert} - \text{butyl bromide}} = \frac{\text{no. of } 1^{\circ}\text{H}}{\text{no. of } 3^{\circ}\text{H}} \times \frac{\text{reactivity of } 1^{\circ}\text{H}}{\text{reactivity of } 3^{\circ}\text{H}}$ tert – butyl bromide

$$=\frac{9}{1}\times\frac{1}{1600}=\frac{9}{1600}$$

Hence, tert-butyl bromide happens to be the exclusive product (over 99%)

Combustion :

 $C_nH_{2n+2} + excess O_2 \xrightarrow{\text{flame}} nCO_2 + (n+1) H_2O$

 ΔH = enthalpy of combusion

Pyrolysis : (Cracking)

3. Decomposition of a compound by heat alone is known as Pyrolysis

Pyrolysis of alkanes particularly when petroleum is concerned is known as cracking.

 $\xrightarrow{400-600^{\circ}C} \mathbf{H}_{2} + \text{smaller alkanes} + \text{alkenes.}$ Alkane with or without catalyst

1

In thermal cracking alkanes are simply passed into a chamber to a high temperature. Large alkanes are converted into smaller alkanes, alkenes and some hydrogen.

<u>Practice Problems</u>:

- The number of possible enantiomeric pairs that can be produced during mono chlorination of 1. 2-methyl butane is
 - 2 3 4 (**d**) **(a) (b)** (c)
- 2. An alkane with molecular mass 72 formed only one substitution product. Suggest a structure for the alkane.

 $\xrightarrow{Na/ether}$ (C). Only one structure of B is possible (A), (B) and 4. 5H11Cl $C_5H_{12} + CI$ (A) **(B)** (C) are :

(a)
$$CH_{3} \xrightarrow{C} - CH_{3} CH_{3} \xrightarrow{C} - CH_{2}Cl$$
 (b) $CH_{3} \xrightarrow{-C} - CH_{2}CH_{3} \xrightarrow{-CH_{3} - CH_{2}-CH_{2}-CH_{2}-CH_{2}-CH_{2}-CH_{2}-CH_{2}-CH_{3} \xrightarrow{-CH_{3} - CH_{3} - CH_{2}-CH_{3}} CH_{3} \xrightarrow{-CH_{3} - CH_{2}-CH_{2}-CH_{2}-CH_{3} \xrightarrow{-CH_{3} - CH_{2}-CH_{2}-CH_{3}} CH_{3} CH_{3}$

(c) [Answers : (1) a (2) a (3) b (4) a]

(d) none is correct

(B) CH₃COCH₃

C3 <u>ALKENES</u>

Methods of Prepration of Alkenes :

1. Dehydrohalogenation of Alkyl-Halide : 1,2 – Elimination

$$- \begin{array}{c} | \\ C \\ - \\ | \\ | \\ H \\ X \end{array} + \begin{array}{c} KOH \\ (alc.) \end{array} \xrightarrow{heat} - \begin{array}{c} | \\ C \\ - \\ C \\ - \\ C \\ - \\ - \\ H \\ X \\ - \\ C \\ - \\ - \\ H \\ X \\ - \\ H \\ - \\ H \\ X \\ - \\ H \\ - \\ H \\ X \\ - \\ H \\ - \\$$

Examples:

$$CH_{3}CH_{2}CH_{2}CH_{2}CH + KOH \xrightarrow{heat} CH_{3}CH_{2}CH = CH_{2}$$

$$CI \xrightarrow{| \\ CH_{3}CH_{2}CHCH_{3} + KOH \xrightarrow{heat} CH_{3}CH = CHCH_{3} + CH_{3}CH_{2}CH = CH_{2}$$

(cis or trans)

Discussion : Dehydrohalogenation means that there is an elimination of one hydrogen atom and one halogen atom. The reagent required is a base, whose function is to remove the hydrogen as a proton. Now if alkyl halide has more than one β , hydrogen atom then that hydrogen is removed which result in more substituted alkene, this is according to saytzeff's rule.

More substituted alkene means that more no. of Alkyl groups are present around the double bond.

e.g.
$$CH_{3}CH_{2} - CH - CH_{3}$$

 β $CH_{3}CH_{2} - CH - CH_{3}$
 α $CH_{3}CH_{2} - CH - CH_{3}$
 $CH_{3}CH_{2}CH = CH_{2}$
(less stable) (minor product)
 $CH_{3}CH_{2}CH = CH_{2}$
(less stable) (minor product)
 $CH_{3}CH_{3}$
 $CH_{3} - C - CH - CH_{3}$
 $H_{3} - C - CH - CH_{3}$
 $CH_{2} = C - CH - CH_{3}$
 H_{3}
 $CH_{2} - C = C - CH_{3}$
 $CH_{3} CH_{3}$
 $CH_{2} - C = C - CH_{3}$
 $CH_{3} CH_{3}$
 $CH_{2} - C = C - CH_{3}$
 $CH_{3} CH_{3}$
 $CH_{2} - C = C - CH_{3}$
 $CH_{3} CH_{3}$
 $CH_{2} - C = C - CH_{3}$
 $CH_{3} CH_{3}$
 $CH_{2} - C = C - CH_{3}$
 $CH_{3} C$

E₂ elimination reactions are chracterised by the following :

- 1. Substrate contains a leaving group; an atom or group that leaves along with electron pair.
- 2. In position β to the leaving group the substrate contain H-atom that can be abstracted by base.
- **3.** Reaction is brought about by a base.

Typically strong bases like OH⁻, RO⁻ (alkoxide ion) derived from alcohol, $C_2H_5O^-$ ethoxide ion, tert-butoxide ion (CH₃)₃CO⁻ etc.

Heterolytic bond dissociation energy : RF > RCl > RBr > RI

 \therefore Reactivity towards E, : RI > RBr > RCl > RF

similarly reactivity order of R - X is $3^{\circ} > 2^{\circ} > 1^{\circ}$

as more substituted alkene will form as the branching will increase.

Kinetics of E_2 : Bimolecular. Rate of the reaction $\mathbf{r} = \mathbf{k} \begin{bmatrix} \mathbf{RX} \end{bmatrix}$ [: Z] Substrate Base

An exception to saytzeff's rule :

$$CH_{3} - CH_{3} - CH_{3} - CH_{3} - CH_{2} - CH_{3} - CH_{2} - CH_{3} + CH_{3} - CH_{3} - CH_{3} + CH_{3} + CH_{3} - CH_{3} + C$$

- The substrate undergo heterolysis slowly to form halide ion and a carbocation.
 In step (2) the carbocation readily looses a proton to the base and forms the alkene.
- 3. Thus a carbocation may
- (a) combine with a nucleophile
- (b) can undergo rearrangement
- (c) eliminate a proton to form the alkene.
- Kinetics of E₁ reaction : r = k [R X] [Unimolecular reaction]
 Order of reactivity of R X for E₁: 3⁰ > 2⁰ > 1⁰
 Thus because of rearrangement skeleton of carbon chain changes :

$$\begin{array}{c} CH_{3} \\ | \\ CH_{3} - C - CHBr - CH_{3} \\ | \\ CH_{3} \end{array} \xrightarrow{(alc.)} (KOH) \xrightarrow{(CH_{3} CH_{3} \\ | \\ CH_{3} - C = C - CH + CH_{3} - CH - C = CH_{2} \\ | \\ CH_{3} - C = C - CH + CH_{3} - CH - C = CH_{2} \\ | \\ CH_{3} \end{array}$$

Alkene that does not contain α -hydrogen in the presence of base can undergo E_1 elimination as follows :

Explanation :

$$\begin{array}{cccc} CH_{3} & CH_{3} CH_{3} CH_{3} CH_{3} CH_{3} CH_{3} CH_{3} \\ CH_{3} - C - CH_{2} - Br & \longrightarrow & CH_{3} - C - CH_{2} \\ \downarrow \\ CH_{3} \end{array} \xrightarrow{} CH_{3} - C - CH_{2} \longrightarrow & CH_{3} - C - CH_{2} \\ \downarrow \\ CH_{3} & & \downarrow \\ CH_{3} & & \downarrow \\ CH_{3} - C = CH & + & CH_{2} CH_{3} CH_{3} \\ \downarrow \\ CH_{3} - C = CH & + & CH_{2} = C - CH_{2} \\ (chief product) \end{array}$$

 $\underline{\mathbf{E}}_{2} \underline{\mathbf{Vs}} \underline{\mathbf{E}}_{1}$

- Reactivity of both mechanism increases with as we move from 1°, 2° to 3° substrate.
- But E, mechanism depends on concentration of base whereas E, mechanism is independent of the concentration of base.
- Stronger the base more E_2 is favoured
- 1º alkyl halide do not favour to form carbocation so they prefer E,
- 2. **Dehydration of Alcohols :**

$$- \begin{array}{c} | & | \\ - C - C - \\ | & | \\ H & OH \end{array} \xrightarrow{acid} - \begin{array}{c} | & | \\ - C = C - + H_2O \end{array}$$

Ease of dehydration of alcohol $3^0 > 2^0 > 1^0$, as the intermediate formed is carbocation.

Examples :
$$H - C - C - H \xrightarrow{acid} H - C = C - H + H_2O$$

 $H - OH Ethylene$

Dehydration is acid-catalyzed :- Acid transforms the poor leaving group (- OH) into the very good leaving group, -OH,+

As dehydration is acid catalysed as acid is hot consumed in the reaction. Acid used in step (1) is regenrated in step (3).

Dehydration is reversible :- Unlike base promoted 1, 2-elimination, this elimination is reversible.

- As we shall study later that acid catalysed the hydration of alkenes to give alcohol.
- Thus each step is reversible.
- Under the condition of dehydration, the alkene being quite volatile is generally driven from the reaction mixture and thus equilibrium (3) is shifted in the right side.
- As a consequence the entire reaction is forced toward elimination.
- Where the structure of alkyl group permits the rearrangement of carbocation takes place.

$$\begin{array}{ccc} CH_{3} & CH_{3} & CH_{3} \\ | & | & | \\ CH_{3}CH_{2}CHCH_{2}OH \xrightarrow{H^{+}} CH_{3}CH = CCH_{3} + CH_{3}CH_{2}C = CH_{2} \\ (Chief Product) \\ According to \\ (Saytzeff's rule) \end{array}$$
Practice Problems :

Identify the possible number of products in the following reaction : $C_6H_5CH_2CH(Cl)C_6H_5$ – 1. **(b)** 2 3 (a) 1 (c) (**d**) 4 [Answers : (1) b]

[Answers : (1) c (2) d (3) d (4) b (5) b (6) b (7) b]

C5 <u>ALKYNES:</u>

Electronic Structure of Triple Bond :

- Acetylene is known to have a linear structure.
- The carbon-hydrogen bond length of 1.06 Å is shorter than that in ethylene or in ethane. Thus it is stronger than either.
- The sp² s σ-bonds are shorter than sp³ s σ-bonds. The trend also holds for the sp s bonds in acetylene.
- Superimposed on the σ -electrons are two orthogonal π -electron system.

Overlap of the p-orbitals on one carbon with the p-orbitals on the other carbon permits pairing of electrons. Two s-bonds are formed, which together make a single cylindrical sheath about the line joining the nuclei.

5.00

- Thus carbon-carbon "triple bond" is thus made up of one strong σ-bond and two weaker π-bonds. It has total strength of 198 kCal. It is stronger than the carbon-carbon double bond of ethylene and carbon-carbon single bond of ethane and is shorter than either.
- 2. Acidity of Alkynes : Very weak acids :
- In our earlier consideration of acids we took acidity to be a measure of the tendency of a compound to loose the hydrogen ion.
- Appreciable acidity is shown by those compounds in which hydrogen is attached to rather electronegative atom like (F > O > N > C). The bond holding the hydrogen is polar, thus relatively positive hydrogen can separate as positive ion, and more electronegative atom can hold the negative charge effectively. In organic chemistry we are frequently concerned with the acidities of compounds do not turn litmus red or neutralize aqueous bases. Yet they have tendency to loose proton H⁺ to small

2

extent. A triply bonded carbon behaved as it is more electronegative than carbon which is singly or double bonded. As a result the hydrogen bonded to terminal alkyne shows the hydrogen bonded to terminal alkyne shows appreciable acidity.

e.g.
$$CH \equiv CH + Na \longrightarrow CH \equiv C^{-} : Na + \frac{1}{2}H_{2}$$

sodium acetylide
 $CH \equiv CH + LiNH_{2} \longrightarrow CH \equiv C^{-}Li^{+} + NH_{3}$
stronger stronger weak weaker
acid base base acid

$HOH + CH \equiv C^- Li^+$ —		\longrightarrow CH = CH + LiOH	
strong	strong	weaker	weak
acid	base	acid	base

<u>Relative Acidities</u>: $H_2O > ROH > HC \equiv CH > NH_3 > RH$ <u>Relative Basicities</u>: $OH^- < OR^- < CH \equiv C^- < NH_2^- < R^-$

If a terminal alkyne is treated with an alkyl magnesium halide or an alkyl lithium the alkane is displaced from its salt and the metal acetylide is obtained.

$$CH_{3} - C \equiv CH + C_{2}H_{5}MgBr \longrightarrow CH_{3} - C \equiv CMgBr + C_{2}H_{6}$$

Strong acid
$$CH_{3}C \equiv CH + CH_{3}CH_{2}CH_{2}CH_{2}CH_{2}Li \longrightarrow CH_{3}CH_{2}CH_{2}CH_{3} + CH_{3}C \equiv C - Li$$

only terminal alkynes give these reaction :

$$CH_{3}C \equiv CH + AgNO_{3} \longrightarrow CH_{3}C \equiv CAg. + HNO_{3}$$

white precipitate
$$CH_{3}C \equiv CH + Cu^{+} \longrightarrow CH_{3}C \equiv CCU (moist)$$

Red(PPt.)

C6. <u>Method of Prepration of Alkynes :</u> Industrial method of preparation :

1. Acetylene is formed from the reaction of inorganic compound calcium carbide with water

$$CaC_{2} + 2H_{2}O \rightarrow Ca(OH)_{2} + CH \equiv CH$$

2.
$$2CH_4 \xrightarrow{1500^{\circ}C} CH \equiv CH + 3H_2$$

3. <u>Laboratory methods of preparation :</u> Dehydrohalogenation of gem or vicinal dihalite :

$$H_3C - CHBr_2 \text{ or } BrH_2C - CH_2Br \xrightarrow{Alc.KOH} CH_2 = CHBr \xrightarrow{NaNH_2} HC \equiv CH + NaBr + NH_3$$

vinyl halide requires the stronger base sodamide NaNH₂.

4. Dehalogenation of vic-tetrahalogen compounds :

$$\begin{array}{c|c} Br & Br \\ | & | \\ CH_3 - C - C - CH_3 + 2Zn & \xrightarrow{C_2H_3OH} & CH - C \equiv C - CH_3 + ZnBr_2 \\ | & | \\ Br & Br & 2-Butyne \end{array}$$

5. <u>Alkyl substitution in acetylene (Method of preparation of higher alkynes) :</u>

$$R - C \equiv CH + NaNH_{2} \longrightarrow R - C \equiv CNa + NH_{3}$$

$$R - C \equiv C Na + CH_{3}CH_{2} - X \longrightarrow R - C \equiv C - CH_{2}CH_{3} + NaX$$

$$HC \equiv CH + 2NaNH_{2} \longrightarrow NaC \equiv CNa + 2NH_{3}$$

$$\downarrow 2n - C_{3}H_{7}Br$$

$$\downarrow C_{3}H_{7} - C \equiv C - C_{3}H_{7}$$

This method is good for synthesis of alkynes when applied to primary halides that do not have branches close to reaction centre. With secondary halide and even with primary halides that have branches closer to the reaction centre, elimination is usually the major reaction.

- C7 <u>Chemical Properties of Acetylene :</u> Addition reaction at the triple bond : π-electrons of alkyne add electrophiles in reactions similar to additions to alkenes. Alkynes can add two moles of reagent but are less reactive than alkenes.
- 1. <u>Hydrogenation</u> $CH_3 C \equiv C CH_2CH_3 + 2H_2 \xrightarrow{Pt} CH_3CH_2CH_2CH_3$

5. <u>Boron hydride :</u>
