## COORDINATION COMPOUNDS

## C1 Double Salts and Co-ordination Compounds

Double Salts : are those which loose their identity in solution as alum. $\left[\mathrm{K}_{2} \mathrm{SO}_{4} \cdot \mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3} \cdot 24 \mathrm{H}_{2} \mathrm{O}\right]$
Co-ordination Compounds (Complexes) : Those which retain their identity in solution (complexes) as potassium ferrocyanide, $\mathrm{K}_{4}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$.
A complex (or co-ordination compound) is a compound consisting either complex ions with other ions of opposite charge.
$\mathrm{K}_{4}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$
complex anion $\quad \mathrm{K}^{+}$is other ion
$\left[\mathrm{Pt}(\mathrm{en})_{3}\right] \mathrm{Cl}_{4} \quad \mathrm{Cl}^{-}$is other ion
complex cation
$\left[\mathrm{Pt}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]$
neutral complex
Ligands : A Ligand is a species that is capable of donating an electron pair(s) to a central ion. It is a Lewis base. In accepting electron pairs, the central ion acts as a Lewis acid.

Ligand can be (a) unidentate
(b) bidentate, tridentate, tetradentate etc.
(c) Ambidient

Unidentate Ligand : Ligand is said to be unidentate if it has only one pair of electrons that it can donate.

Polydentate Ligand : Ligand is said to be bidentate, tridentate, tetradentate etc. depending on the number of electron pairs that it can donate.
(a) : $\mathrm{NH}_{3}$; one electron pair available for donation oxidentate.
(b)

## Some common Multidentate Ligands (Chelating Agents)

Abbrevation

en Multi \begin{tabular}{l}
Name <br>
bidentate

$\quad$

Formulae <br>
ox
\end{tabular}

DMG bidentate dimethylglyoximate

EDTA
hexadentate

tetraacetate
Chelates: Some ligands are capable of donating more than a single electron pair, from different atoms in the ligand and to different sites in the geometric structure of a complex. These are called as multidentate ligands. When the bonding of a multidentate ligand to metal ion produces a ring (usually five or six membered) we refer to the complex as a chelate. The multidentate ligand is called a chelating agent and the process of chelate formation is called chelation

## Nickel (II) dimethylglyoximate (chelate)

[bis-(dimethylglyoximato) nickel (II)]
Co-ordination Number : The co-ordination number of a metal atom in a complex is the total number of bonds the metal atomforms with Ligands.

C2A Nomenclature : Following rules are adopted for naming a complex ion.
(a) cations are named before anions.
(b) oxidation state (O.S.) of the centralmetal ion is denoted by Roman numeral

## Cation O.S. Anion

$\mathrm{CuC}_{2}$
$\mathrm{FeCl}_{3}$

Copper (II) chloride
Iron (III) chloride
(c) The names of ligands are given first followed by the name of central metal ion.
(d) The names of ligands that are anions and ending with
'ide' changed to ' o '
'ite' changed to 'ito'
'ate' changed to 'ato'

## CCC - 4

(e)

## Some Common Unidentate Ligands

| Neutral |  |
| :--- | :--- |
| Formula | Names as Ligand |
| $\mathrm{H}_{2} \mathrm{O}$ | aqua |
| $\mathrm{NH}_{3}$ | ammine |
| CO | Carbonyl |
| NO | nitrosyl |
| $\mathrm{CH}_{3} \mathrm{NH}_{2}$ methyl amine |  |
| $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$ or Py | Pyridine |
| $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{3} \mathrm{~N}$ | Triethylamine |
| $\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3} \mathrm{~N}$ | Tripphenyl amine |
| $\left[{ }^{*}\right.$ marked are ambident) |  |

Anions (replacing 'ide' by ' 0 ')
Formula

F-(Fluoride) Fluorido
$\mathrm{Cl}^{-} \quad$ Chlorido
$\mathrm{S}^{-2}$ sulphido
$\mathrm{H}^{-} \quad$ hydrido
$\mathrm{O}^{-2}$ (oxide) oxo
$\mathrm{OH}^{-}$(hydroxide) hydroxo
$\mathrm{CN}^{-}$(cyanide) cyano*
NC isocyano*
[* marked are ambident)

| Replacing 'e' by ' 0 ' |  |
| :---: | :---: |
| $\mathrm{SO}_{4}{ }^{2-}$ | sulphato |
| $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$ | thiosulphato |
|  | carbonato |
| $\mathrm{NO}_{2}{ }^{-}$ | nitro* |
| ONO | nitrito* |
| SC | thiocyanato* |
| $\mathrm{NCS}^{-}$ | isothiocyanato* |

(e) Positive groups end in-ium
$\mathrm{NH}_{2}-\mathrm{NH}_{3}{ }^{+}$hydrazinium
(f) When there are several ligands of the same kind we normally use the prefix di, tri, tetra soon. If the name of ligand includes a number e.g. ethylenediamine (en). To avoid confusion in such cases, bis, trix and tetrakis are used.
e.g. bis (ethylenediammine)
(g) If anion is a complex then metal ends with 'ate' $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$

## tetracyanonickelate (II) ion

| lead - plumbate | gold - Aurate |
| :--- | :--- |
| tin - stannate | silver - argentate |
| iron- ferrate | copper - cuprate |

(h) If the complex contain two or more metal atoms, it is termed polynuclear. The bridging ligands which link the two metal atoms together are indicated by the prefix
(i) Ambidient Ligands may be attached through different atoms

$$
\begin{array}{ll}
\mathrm{M}-\mathrm{NO}_{2} & \left(\mathrm{NO}_{2}\right) \text { joined to metal } \mathrm{M} \text { through } \mathrm{N} \text {; it is nitro } \\
\mathrm{M}-\mathrm{ONO} & \left(\mathrm{NO}_{2} \text { joined to metal } \mathrm{M} \text { through } \mathrm{O} \text { it is nitro }\right)
\end{array}
$$

Similarly the SCN group may bond M-SCN (thiocyanato) or (M - NCS) (isothiocyanato). They may be named as

$$
\text { thiocyanato }-\mathrm{S}, \quad \text { thiocyanato }-\mathrm{N}
$$

## C2B When writing (not naming) the formulae of the complex

- complex ion should be enclosed by square brackets.
- Ligands are place after metal in the alphabetical order but first negative ligands, then neutral then positive.

## Example :-

1. $\underset{\text { cation }}{\mathbf{K}_{4}} \frac{\left[\mathrm{Fe}(\mathbf{C N})_{6}\right]}{\text { Anion }}$

Potassium hexacyanof errate(II)
cation anion

- anion is complex hence metal ends with ate.
- Ligands are named before metal ion of complex.

2. $\frac{\left[\mathrm{CO}\left(\mathrm{NH}_{3}\right)_{6}\right]}{\text { cation }} \underset{\text { anion }}{\mathrm{Cl}_{3}}$

Hexaammine cobalt (III) chloride
3. $\left[\mathrm{CO}(\mathrm{en})_{3}\right]_{3}$

Tris (ethylenediammine) cobalt (III) chloride
4. $\quad\left[\mathrm{Pt}(\mathrm{Cl})_{2}\left(\mathrm{NH}_{3}\right)_{4}\right] \mathrm{Cl}_{2}$

Tetraamminedichloroplatinum (IV) chloride
$\left[\mathrm{NH}_{3}\right.$ (ammine) and Cl (chloro) are written in alphabetical order]

## 5. In the following examples complex ion exist as cation :-

(a) $\quad\left[\mathrm{Fe}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$ Hexaammine iron (III) chloride
(b) $\quad\left[\mathrm{CoCl}\left(\mathrm{NH}_{3}\right)_{5}\right]^{2+}$ Pentaamminechlorocobalt (III) ion
(c) $\left[\mathrm{CoSO}_{4}\left(\mathrm{NH}_{3}\right)_{4}\right] \mathrm{NO}_{3}$ Tetraamminesulphatocobalt (III) nitrate
6. Complex ion exist as anions :-
(a) $\quad\left[\mathrm{ZnCl}_{4}\right]^{2-}$ Tetrachlorozincate (II) ion
(b) $\left[\mathrm{AlH}_{4}\right]^{-}$Tetrahydridoaluminate (III) ion
(c) $\mathrm{Na}_{3}\left[\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}\right]$ Sodium bis (thiosulphato) argentate (I)
(d) $\quad \mathrm{Na}_{2}\left[\mathrm{OSCl}_{5} \mathrm{~N}\right]$ sodium pentachloronitrido osmate (VI)
(e) $\quad \mathrm{K}_{2}\left[\mathrm{Cr}(\mathrm{CN})_{2} \mathrm{O}_{2}\left(\mathrm{O}_{2}\right) \mathrm{NH}_{3}\right]$ Potassium amminedicyanodioxo peroxochromate (VI)

## 7. Organic Ligands have been used :-

(a) $\quad\left[\mathrm{Pt}\left(\mathrm{Py}_{4}\right)_{4}\right]\left[\mathrm{Pt} \mathrm{Cl}_{4}\right]$ Tetrapyridineplatinum (II) tetrachloroplatinate (II)
(b) $\quad\left[\mathrm{Cr}\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)_{2}\right]$ Bis (benzene) chromium (O)
(c) $\quad\left[\mathrm{Fe}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2}\right]$ Bis (cyclopentadienyl) iron (II)

## C2C (EAN) Effective Atomic Number :

Each ligand donates an electron pair to the metal ion, thus forming a co-ordinate bond

$$
\text { EAN }=Z-\text { O.N. }+2 \text { (C.N.) }
$$

$$
\mathrm{ON} \rightarrow \text { oxidation number }
$$

or $\quad$ C.N. $\rightarrow$ co-ordination number
EAN $=\mathrm{Z}-\mathrm{O} . \mathrm{N} .+2$ (Ligands) (assuming that each ligand is unidentate)

## C3 Isomerism in Complexes :-

Compounds having same chemical formulae but differ structural arrangements are called isomers.

## Structural isomerism :-

Differ from each other. How the atoms are joined together that is in the order in which the atoms are bonded to each other.
$\mathrm{H}-\mathrm{N}=\mathrm{C}=\mathrm{O}$ and $\mathrm{N} \equiv \mathrm{C}-\mathrm{O}-\mathrm{H}$ are structural isomer.

## Ionisation Isomerism :-

This type of isomerism occurs when there is an interchange of groups between the ordination sphere of the metal ion and the ions outside this sphere. Examples are :
$\left[\mathrm{CO}\left(\mathrm{NH}_{3}\right)_{5}\left(\mathrm{SO}_{4}\right] \mathrm{Br}\right.$
$\left[\mathrm{CO}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Br}\right] \mathrm{SO}_{4}$
[give yellow ppt. with $\mathrm{Ag}^{+}$[give white ppt. with $\mathrm{Ba}^{2+}$ as $\mathrm{SO}_{4}{ }^{2-}$ being ion as $\mathrm{Br}^{-}$outside the bracket ionisable]
is ionisable]

## Co-ordination isomerism :-

When both positive and negative ions are complex ions. Isomerism may be caused due to interchange of ligands between anion and cation. This arises only when cation and anion have same C.N. and charge
(a) $\begin{aligned} {\left[\mathrm{CO}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}\left[\mathrm{Cr}(\mathrm{CN})_{6}\right]^{3-} } & \text { same charge } \\ & \& \\ & {\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}\left[\mathrm{CO}(\mathrm{CN})_{6}\right]^{3-} }\end{aligned}$

## Linkage Isomerism :-

(i) $\left[\mathrm{CO}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{ONO}\right] \mathrm{Cl}_{2}$ and $\left[\mathrm{CO}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{NO}_{2}\right] \mathrm{Cl}_{2}$
(ii) $\left[\mathrm{Mn}(\mathrm{CO})_{5}(\mathrm{SCN})\right]^{+} \quad\left[\mathrm{Mn}(\mathrm{CO})_{5}(\mathrm{NCS})\right]^{+}$

## Hydrate Isomerism :-

Hydrate isomers of a complex that differ in the placement of water molecules in the complex $\mathrm{CrCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ can be written as

| $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{Cl}_{3}$ | - | violet (anhydrous) |
| :--- | :--- | :--- |
| $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{Cl}^{2}\right] \mathrm{Cl}_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ | - | light green (monohydrate) |

## Stereo Isomers :-

1. Geometrical

## 2. Optical

Geometrical :- are isomers in which the atoms are joined to one another in the same way but differ because some atom occupy different relative position in space.

## Geometrical Isomers of C.N. - 4

(a) $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$

cis
(orange yellow)

trans
(pale yellow)
(b)

Geometrical isomers of C.N. - 6
(a) $\left[\mathrm{CO}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$

Trans

Cis
(b) $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}_{2} \mathrm{Br}_{2}\right]$

Cis

Trans
(c) $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}_{3}\right]$

Facial
(Fac.)

Meridianal
(Mer.)

Optical Isomerism :- If a molecule is asymetric that it cannot superimposed on its mirror image. The two forms have the same type of symmetry shown by the left and right hands and are called enantiomeric pair. The two forms are called optical isomers. They are called either dextro or leavo (dor l).

Optical isomerism is common in octahedral complexes involving bidentate ligands. $\left[\mathrm{CO}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]$ exists as cis and trans but cis-form can have optical isomerism.

trans

Cis

$\left[\mathrm{CO}(\mathrm{en})_{3}\right]^{3+}$

enantiomeric pair (d and l)

## C4A Werner's theory of co-ordination compounds :

1. There are two types of valency shown by central metal atom/metal ion in a compound
(a) Primary
(b) Secondary

- Primary Valency corresponds to oxidation number and secondary valency corresponds to co-ordination number.
- In the complex $\left[\mathrm{CO}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$, primary valency is satisfied by three Cl , secondary valency is six.
- In $\left[\mathrm{CO}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \mathrm{SO}_{4}$, four $\mathrm{NH}_{3}$ and two $\mathrm{H}_{2} \mathrm{O}$ (ligands) satisfy secondary valency.
- One $\mathrm{SO}_{4}^{2-}$ satisfy primary valency.
- Primary valency is ionisable.
- The secondary valencies are directional and are responsible for isomerism in complexes.
- The primary valencies are non-directional and is represented by $\qquad$ and secondary valency by $\qquad$
- In all cases, metal or metal ions should satisfy primary and secondary valency both. Some negative ions can satisfy primary as well as secondary valency both.
e.g. $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}$ satisfy both primary and secondary valency.

## Practice Problems :

1. Explain the bonding in coordination compounds in terms of Werner's postulates.

## C4B Bonding in complexes

- The metal $m$ loses required no. of electrons to form cation. No. of electrons lost correspond to O.N.
- The metal ion makes available a no. of empty orbitals equal ot its co-ordinates number for the formation of co-ordinates bonds with the Ligand Orbitals.
- A weak ligand like $\left(\mathrm{H}_{2} \mathrm{O}\right.$, halide) will not affect the electronic configuration of the metal/ metal ion.
- A strong ligand like $\left(\mathrm{NH}_{3}, \mathrm{CN}^{-}, \mathrm{CO}\right)$ affect the electronic configuration of the metal/ metalion. They make unpaired electrons paired.
- The metal ion orbitals hybridise to form a new set of equivalent hybridised orbitals.
- If there are unpaired electrons in the complex it is called paramagnetic.

Magnetic moment $=\sqrt{\mathrm{N}(\mathrm{N}+2)}$ B.M.
$\mathrm{N} \rightarrow$ no. of unpaired electrons.

- The complex with so many unpaired electrons is high spin complex and that with paired electrons is low spin complex.
- If inner d-orbital is used for hybridisation it is called inner d complex. e.g. $d^{2} \mathrm{sp}^{3}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{4}$
- If outer d-orbital is used is called outer d-complex. $\mathrm{sp}^{3} \mathrm{~d}^{2}$

Weak field ligand $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$

- $\mathrm{I}^{-}<\mathrm{Br}<\mathrm{S}^{2-}<\mathrm{Cl}^{-}<\mathrm{NO}_{3}^{-}<\mathrm{F} \ll$ oxalate $<\mathrm{H}_{2} \mathrm{O}<\mathrm{EDTA}<\mathrm{NH}_{3}<\mathrm{en}<\mathrm{NO}_{2}^{-}<\mathrm{CN}^{-}$ $<\mathrm{CO}$

Examples: $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{-} \quad$ O.N. $=+2$

$$
\text { C.N. }=6
$$

[six empty orbitals are required by six $\mathrm{CN}^{-}$ligands] $\mathrm{t}_{2} \mathrm{~g} \rightarrow \mathrm{~d}_{\mathrm{xy}}, \mathrm{d}_{\mathrm{yz}}, \mathrm{d}_{\mathrm{zx}}$ e.g. $\mathrm{dx}^{2}-\mathrm{y}^{2}, \mathrm{dz}^{2}$

- Complex ion is $\mathrm{d}^{2} \mathrm{sp}^{3}$ hybridised
- Diamagnetic
- Octahedral geometry
$\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\right.$

$\left(\mathrm{H}_{2} \mathrm{O}\right.$ is weak ligand)
- Hybridisation $-\mathrm{sp}^{3} \mathrm{~d}^{2}$
- Paramagnetic (High spin complex)

Inner d-complex

- Magnetic moment $=0$
